

```
class_name obj1, obj2;  
obj1=obj2;
```

It is an overloaded constructor.

It is an operator.

It creates a new object as a copy of an existing object.

It assigns the value of one object to another object both of which already exist.

The copy constructor is used when a new object is created with some existing object.

It is used when we want to assign an existing object to a new object.

Both the objects use separate memory locations.

Both objects share the same memory but use the two different reference variables that point to the same location.

If no copy constructor is defined in the class, the compiler provides one.

If the assignment operator is not overloaded then the bitwise copy will be made.

24) What is the difference between Composition and Inheritance?

Inheritance means an object inheriting reusable properties of the base class. Compositions mean that an object holds other objects. In Inheritance, there is only one object in memory (derived object) whereas, in Composition, the parent object holds references of all composed objects. From a design perspective, inheritance is "is a" relationship among objects whereas Composition is "has a" relationship among objects.
