

- Frame synchronization: Data-link layer converts the data into frames, and it ensures that the destination must recognize the starting and ending of each frame.
- Flow control: Data-link layer controls the data flow within the network.
- Error control: It detects and corrects the error occurred during the transmission from source to destination.
- Addressing: Data-link layer attach the physical address with the data frames so that the individual machines can be easily identified.
- Link management: Data-link layer manages the initiation, maintenance and, termination of the link between the source and destination for the effective exchange of data.

3. Network Layer

- Network layer converts the logical address into the physical address.
- It provides the routing concept means it determines the best route for the packet to travel from source to the destination.

Functions of network layer:
